

Smith study methods.

Smith used 30 silicon cells.

Smith measured at temperatures from 20 to 60 degrees Celsius.

Smith used a four-wire measurement method.

Smith study results.

Smith reported a temperature coefficient of -0.40 percent per kelvin.

Smith observed a contact resistance of 0.2 to 0.4 ohms.

Smith observed larger relative measurement error at low frequencies.

Smith study limitations.

The Smith study was limited to silicon cells.

Smith did not establish performance for heterojunction modules.
